- Real-time applications have been widely spread. (e.g. audio/video conferencing and IP telephony)
 - Large end-to-end delay lowers the quality of real-time applications.
 - It is often necessary to accurately estimate end-to-end delay and evaluate path quality.
-
- Active measurement is one representative measurement technique for end-to-end delay.

Conclusion and future
works

- A problem with active measurement is that probe traffic increases network delay.

Objective

- To estimate the delay of a network without probe packets from the delay of that same network with probe packets.

Conclusion and future
works

- An accurate estimator must have a smaller variance and a smaller bias.

- We evaluate estimators by using Mean Square Error (MSE).

$$(\text{MSE}) = \underbrace{\text{Var}[\hat{P}]}_{\text{Variance}} + \underbrace{\{\text{E}[\hat{P}] - P^*\}^2}_{\text{Bias}} = \text{E}[(\hat{P} - P^*)^2] \quad (1)$$

\hat{P} : Estimator

P^* : True value

To transcend that bound, we propose INTrusiveness-aware ESTimation (INTEST), **an approach that modifies for delays increased by probe packets for networks.**

- We can know increment of delay using the information of the number of probe packets.

works

- For busy period $[s_j, e_j]$, delay $D_{gp}(T_i)$ experienced by a probe packet can be expressed by the following:

$$D_{gp}(T_i) = D_{gp}(T_{i-1}) + \frac{X_{gp}(T_i, T_{i-1})}{c} - (T_i - T_{i-1}), \quad (s_j \leq T_i \leq T_{i-1} \leq e_j)$$

T_i : Time of an arrival of i th probe packet

c : Bandwidth [bps]

$X_{gp}(t_0, t_1)$: traffic in a period $[t_0, t_1)$ [bit]

- Busy periods can be estimated by probe delay.
- Based on the above equation, **we can modify the increment of delay** since the traffic of probe packets in $X_{gp}(T_i, T_{i-1})$ is known.

Conclusion and future
works

- We can estimate the true delay by the following recurrence equation.

Decreasing the increased delay
by probe traffic

Busy case and idle case

$$\hat{D}_g(T_i) = \begin{cases} \max\left(\hat{D}_g(T_{i-1}) + D_{gp}(T_i) - D_{gp}(T_{i-1}) - \frac{x_{i-1}^p}{\hat{c}}, \hat{d}\right), & \hat{s}_j \leq T_i \leq \hat{e}_j \\ D_{gp}(T_i), & \text{otherwise.} \end{cases}$$

$\hat{D}_g(T_i)$: The delay of the network without probe packets at time T_i

x_i^p : The size of i th probe packets [bit]

\hat{s}_j : j th smallest element of $\{T_i \mid D_{gp}(T_{i-1}) \leq d + \delta < D_{gp}(T_i)\}$

\hat{e}_j : j th smallest element of $\{T_i \mid D_{gp}(T_{i-1}) \geq d + \delta > D_{gp}(T_i)\}$

- \hat{s}_j and \hat{e}_j are estimators of start and end time of a busy period, respectively.

Evaluation in M/M/1

Evaluation through
ns-3 Simulations

Conclusion and future
works

- We calculated the MSE by repeating the simulation 5000 times.
- INTEST can achieve accurate estimation though the conventional estimator has accuracy bounds.

Evaluation through ns-3 Simulations

K. Watabe
K. Nakagawa

- We performed INTEST in ns-3 simulation.

Bandwidth of N_1-N_2 and N_2-N_3 : 15.552 Mbps

Bandwidth of the other links : 62.208 Mbps

Probe packet size : 64 byte

Packet size of the other traffic : 600 byte

Target traffic rate : 10% of the bottleneck bandwidth

Cross traffic pattern : ON-OFF process in which ON/OFF period follows exponential distribution with mean 0.5 sec

Cross traffic rate : 8 Mbps

In this paper, we demonstrated that there exists a fundamental accuracy bound to conventional active measurement of delay and **proposed INTEST that estimates the delay of a network without probe packets** from the delay of that same network with probe packets.

- INTEST modify the increased delay by the load imposed by probe traffic.
- Performing simulations of M/M/1 and ns-3, we demonstrated that INTEST provides unbiased and small variance estimation.

Future works

- Evaluation of INTEST on a real network.
- To extend it to packet loss estimation and to wireless networks.
